

Section 2.1 How Do We Measure Speed?

Consider the table which shows the height of a grapefruit at t seconds.

$t(\text{sec})$	0	1	2	3	4	5	6
$s(t) = y(\text{feet})$	6	90	142	162	150	106	30

If $s(t)$ is the position of an object at time t , then the average velocity from $t=a$ to $t=b$ is

$$\frac{s(b) - s(a)}{b - a} = \frac{\text{change in position}}{\text{change in time}}$$

ex: Find the avg. Velocity for $4 \leq t \leq 5$

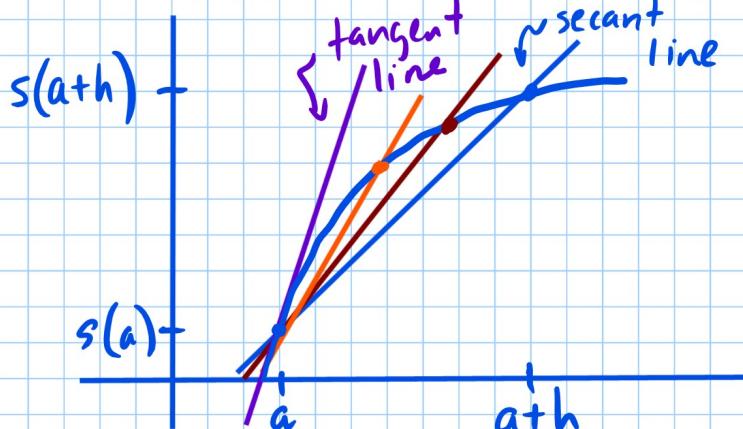

$$\frac{s(5) - s(4)}{5 - 4} = \frac{106 - 150}{1} = -44 \text{ ft/sec}$$

↑ going down

ex: Find the avg. velocity for $1 \leq t \leq 3$

$$\frac{s(3) - s(1)}{3 - 1} = \frac{162 - 90}{2} = \frac{72}{2} = 36 \text{ ft/sec}$$

What if we wanted instantaneous velocity at $t=a$?

avg. velocity from
 $t=a$ to $t=ath$

$$\frac{s(ath) - s(a)}{ath - a}$$

$$= \frac{s(ath) - s(a)}{h}$$

If we let $a+h$ approach a , the average velocity gets closer to becoming the instantaneous velocity.

slope of the secant line

We can say therefore that

$$\text{instantaneous velocity at } t=a = \lim_{h \rightarrow 0} \frac{s(a+h) - s(a)}{h}$$

As $h \rightarrow 0$, the secant line joining $(a, s(a))$ and $(a+h, s(a+h))$ approaches the tangent line at $(a, s(a))$. So instantaneous velocity is the slope of the tangent line.

Slope of tan line at $x=a$ means the same as the slope of the curve at $x=a$.

ex 2 p61 $s = 3t^2$

a) $s=1$ to $s=1+h$
when $h=0.1$

$$\frac{1+h}{1+0.1}$$

$$\frac{s(1.1) - s(1)}{1.1 - 1} = \frac{3 \cdot 1.1^2 - 3 \cdot 1^2}{0.1}$$

$$= \frac{3.63 - 3}{0.1}$$

$$= 6.3 \text{ m/sec}$$

b) $s=1$ to $s=1+h$
when $h=0.01$

$$\frac{s(1.01) - s(1)}{1.01 - 1} = \frac{3 \cdot 1.01^2 - 3 \cdot 1^2}{0.01} = \frac{3.0603 - 3}{0.01} = 6.03 \text{ m/sec}$$

We predict inst. velocity is 6 m/sec when t = 1 sec.

$$\begin{aligned}\text{Inst. velocity at } t=1 &= \lim_{h \rightarrow 0} \frac{s(1+h) - s(1)}{h} \\&= \lim_{h \rightarrow 0} \frac{\cancel{s(1+h)}}{h} - \frac{\cancel{s(1)}}{h^2} \\&= \lim_{h \rightarrow 0} \frac{3(1+h)^2 - 3 \cdot 1^2}{h} \\&= \lim_{h \rightarrow 0} \frac{3(1+2h+h^2) - 3}{h} \\&= \lim_{h \rightarrow 0} \frac{\cancel{3} + 6h + 3h^2 - \cancel{3}}{h} \\&= \lim_{h \rightarrow 0} \cancel{h}(6 + 3h) \\&= 6 + 3 \cdot 0 \\&= 6\end{aligned}$$
